- Prof. Azad Madni, Principal Investigator
- Prof. Dan Erwin, Co-Investigator
- Dr. Ayesha Madni, Project Manager
- Edwin Ordoukhanian, Research Assistant
- Parisa Pouya, Research Assistant
- Shatad Purohit, Research Assistant

- Research Objectives
- Accomplishments Summary
- Technical Approach
- Prototype System
- Findings and Lessons Learned
- Technology Transition

- Investigate innovative approaches for developing next generation adaptive CPHS in which human(s) and cyber-physical (CP) elements collaborate in joint task performance and adapt as needed to respond to operational contingencies and disruptions
- **Illustrative Application:** Perimeter security of C-130 aircraft parked on a landing strip and secured by fixed and mobile collection assets

- High complexity (hyper-connectivity, interdependencies)
- Need to operate safely for extended periods in dynamic, uncertain environments subject to disruptions
- Long-lived (> 20 years)
- Likely to be extended / adapted over lifetime
- Stringent physical and cyber security requirements
- Adaptive and distributed autonomy

Need new modeling methods and tools

- A class of safety-critical socio-technical systems in which interactions between *physical system* and *cyber elements* that control its operation are influenced by *human agent(s)*
- System objectives achieved through interactions between:
 - **Physical system** (or process) to be controlled
 - **Cyber elements** (i.e., communication links and software)
 - **Human agents** who monitor and influence cyber-physical system operation
- **Distinguishing Feature:** Human (agents) intervene to:
 - redirect cyber-physical elements or supply needed information
 -not just to exercise manual over-ride or assume full control

- Safety-critical systems - range from small devices to SoS
 - Self-Driving Vehicles
 - Smart Buildings
 - Smart Manufacturing
 - Medical Devices
 - Unmanned Aerial Vehicles

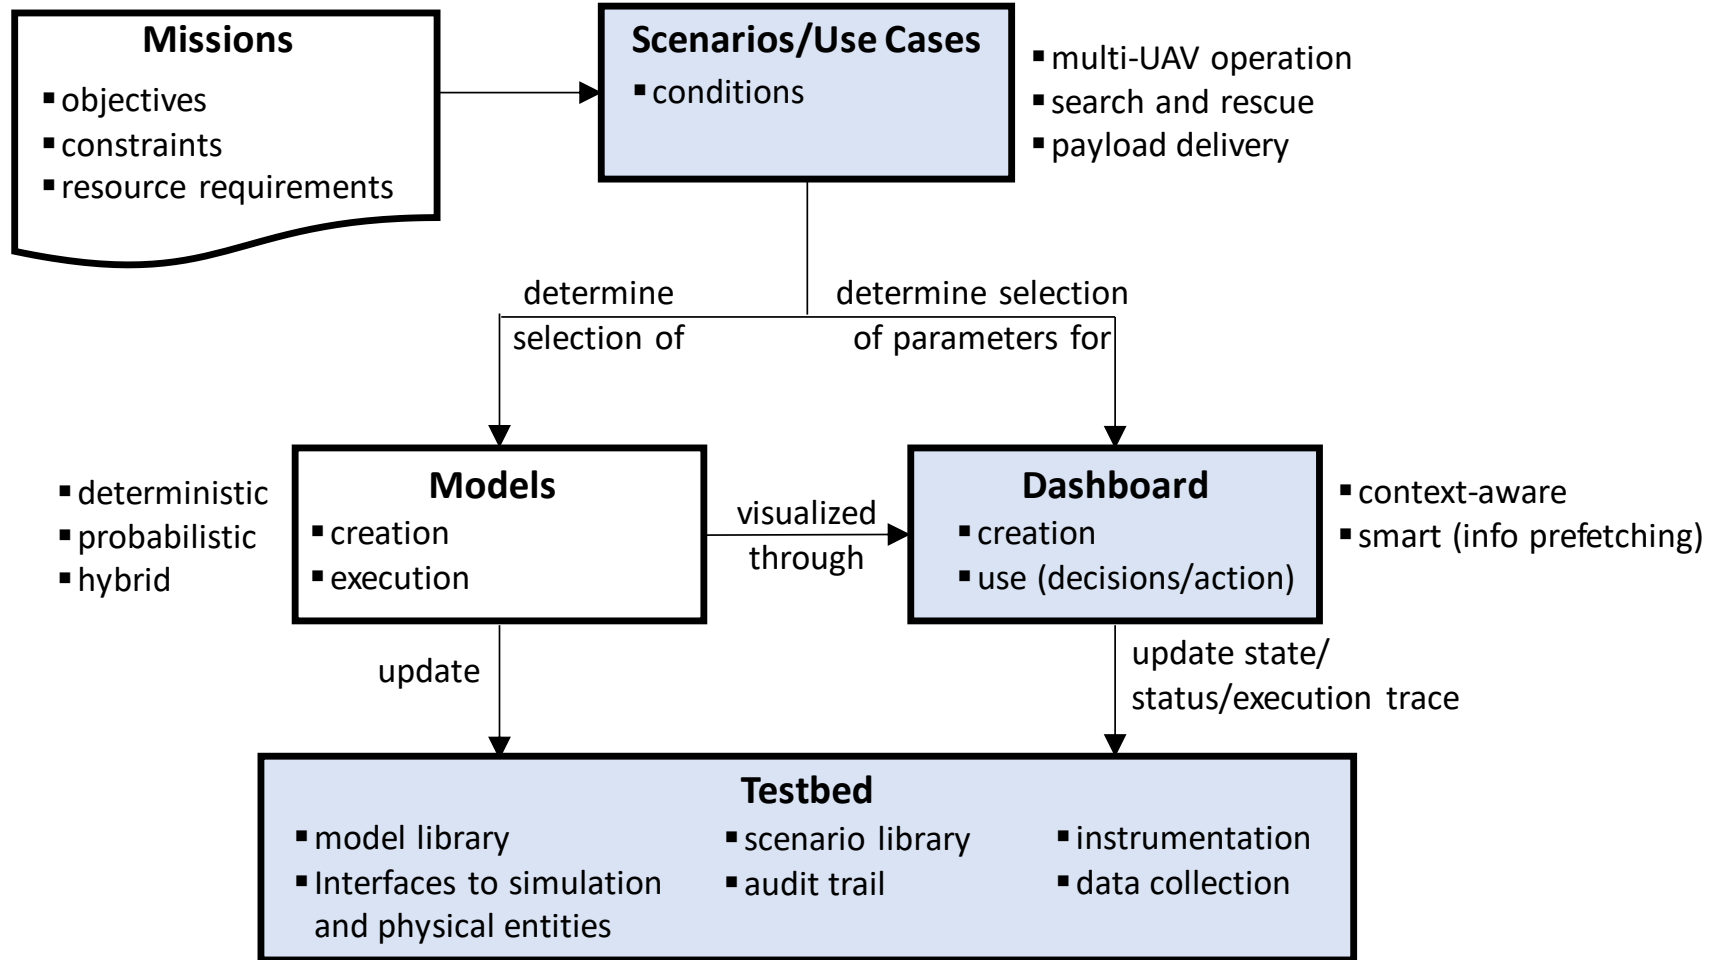

- **Respond** to disruptions and changes in context
- **Exploit synergy** between humans and CPS
- **Capitalize on** unique human capabilities, while circumventing human limitations
- **Leverage** CPS strengths while circumventing CPS limitations
- **Learn** from experience (observations, outcomes) using ML

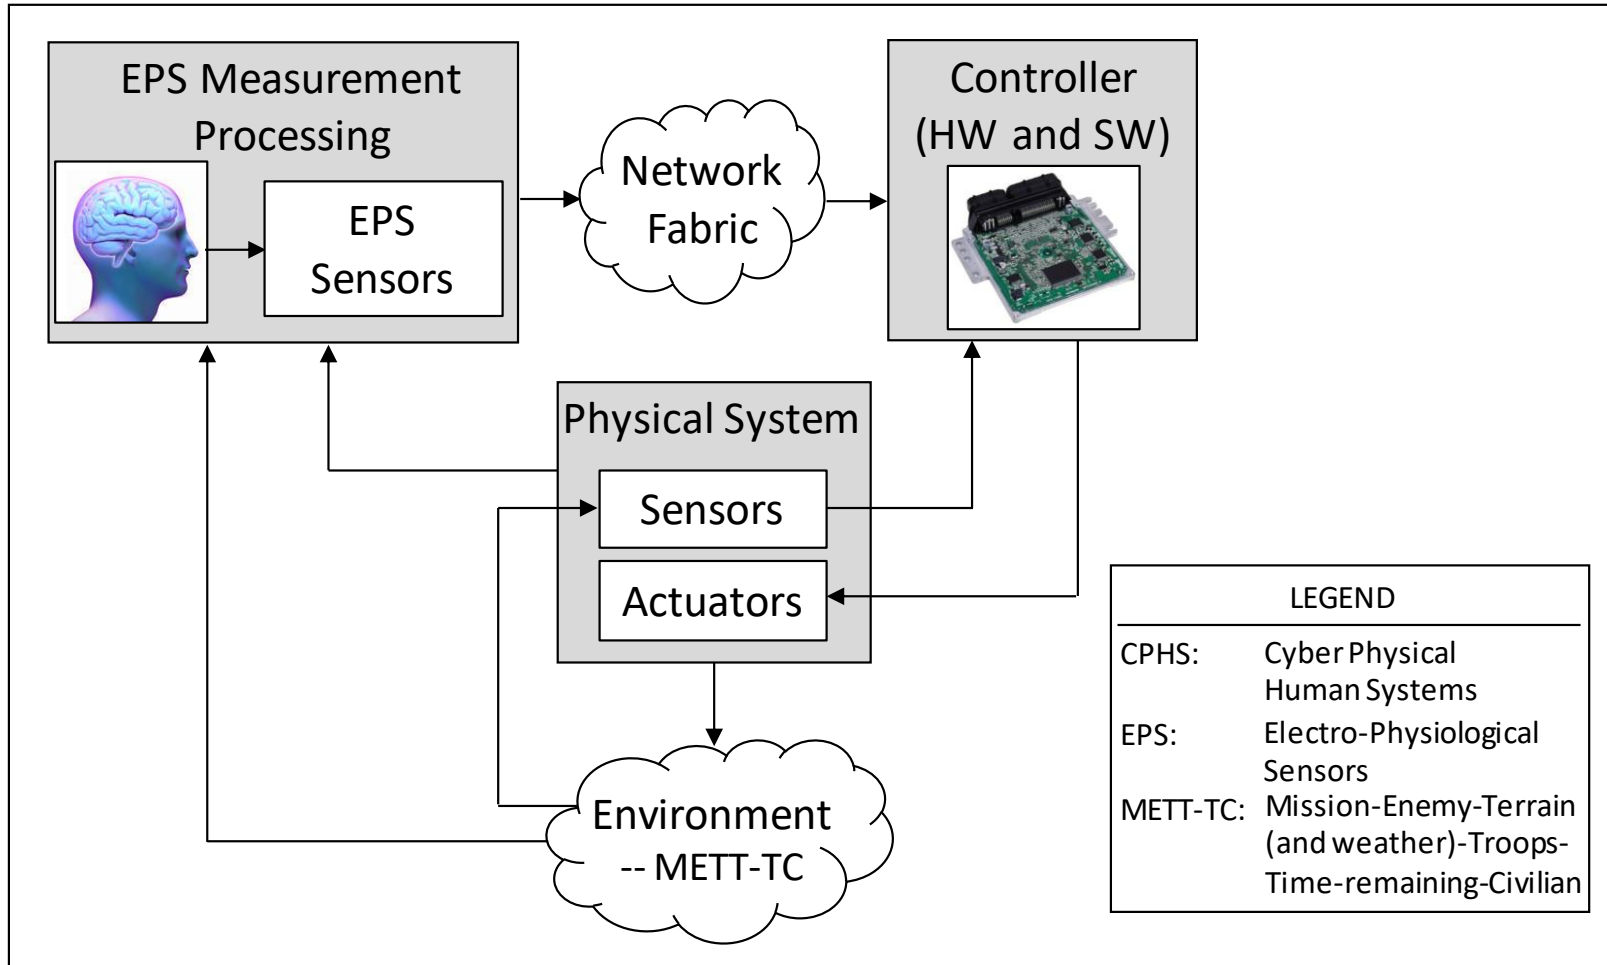

Deficiencies in Existing Modeling Methods and Tools

- **Methods:** Ill-suited for tightly-coupled, sociotechnical learning systems – do not have:
 - semantics of time
 - ability to improve with use
 - flexible representation of human behavior
 - learning ability (offline, in-situ)
- **Tools:** reflect methodological deficiencies
 - address cyber, physical, and human elements in isolation
 - focus primarily on subsystems, not their interactions and dependencies
and synchronization constraints
 - “build-time” approaches -- no “run-time” learning

Technical Approach

- Leverage models from RT-210
 - formal and probabilistic modeling
 - machine learning
- Adaptive CPHS Research Focus
 - interactive planning and decision making
 - supervisory and autonomous control
 - geographic region coverage optimization
 - human behavior modeling
- Context-aware (“smart”) dashboard
 - context defined by a formal ontology (METT-TC)
 - multi-perspective, multilevel, with visual cueing
- Testbed Capabilities
 - support adaptive CPHS research focus areas
 - support data collection and maintain audit trail
 - control both virtual simulation models and physical systems

- **Monitor/Supervisor:** outside the control loop
 - monitor and interact with environment (CPS unaware of this interaction)
 - assess correctness of operation of CPS; approve CPS decision
 - intervene at appropriate level in control loop (context: CPS requests take over; incorrect or error-prone CPS behavior; over-ride erroneous CPS decision)
 - re-allocate tasks (context: cognitive overload/fatigue; CPS request)
- **Controller:** within the control loop
 - intervene at appropriate level in control loop (context: have new / missing info)
 - e.g., redirect sensors / collection assets; supply missing information
 - e.g., modify actuator inputs based on info unavailable to controller
- **Backup:** within the control loop
 - assume CPS control function (context: when CPS malfunctions, or CPS requests human takeover, or CPS fails to respond in allotted time)

Adaptation Type	Triggering Criteria	Desired Outcome
Re-allocation of Task(s) from Human to Machine	Human Cognitive load exceeds threshold; Fatigue; Human error rate exceeds threshold	Manageable human cognitive load; Acceptable error rate
Re-allocation of Task(s) from Machine to Human	Novel situation (unrecognizable by CPS); CPS request; CPS malfunction	Proper handling of novel situations/contingencies
Machine Adapts to Human	Change in human preference structure and information seeking policy	Increased S/N ratio information delivered to human especially under time-stress
Human Adapts to Machine	Machine request to transfer control; change of context requires transfer of control	Superior ability to deal with operational tasks and situation

- Scope is a function of human roles in the adaptive CPHS
- Need to ensure that the adaptive CPHS is operating within human cognitive constraints while capitalizing on human strengths
 - effects of cognitive load, fatigue, and attention level on error rates
- Key research questions:
 - What aspects of humans to represent for specific problem contexts?
 - Is there a methodological basis to determine an appropriate sparse representation of a human?
 - At what level should human (model) be incorporated in feedback loop (e.g., on-the-loop, in-the-loop, inside controller, inside system model)?
 - What modeling approach (e.g., HMM, MAU decision models, optimal control model) best fits a particular problem context?

- Different ML techniques for different uses in Adaptive CPHS
- **Reinforcement Learning:** Discover unidentified environment states from observations during mission execution
- **Supervised Learning:** Capture human preferences offline from simulated task performance in different contexts
- **Unsupervised Learning:** Discover behavior patterns from data in different contexts

Prototype System Implementation

Illustrative Scenario: Perimeter Security of C-130 Aircraft

- Multiple QCs with downward-facing video cameras
- Building-mounted video and Long Wave Infrared (LWIR) cameras
- QCs change and hold position and altitude that maximizes a collective fitness function (FF)
 - FF reflects perimeter coverage
 - QCs can change position and altitude to maximize FF

- **Contingencies1:** low battery causing QC to land; loss of QC

Resilience responses: reposition remaining QCs to restore coverage; launch backup QC if repositioning does not work

- **Contingencies2:** Intruder in the secured field

Resilience responses: collect motion data and extract features; use an ML technique to classify foes from friends; respond autonomously while keeping commander in the loop, or request commander intervention to respond

- **Segment #1:** Navigate to target area with partial observability
 - account for uncertainty and adjust route with observations
 - monitor system health during route to target area
- **Segment #2:** Maximize perimeter coverage with available static and mobile sensors
 - detect intrusion and notify commander (intrusion location, action)
 - Request commander to confirm intruder (if ambiguous to autonomous agent)
 - tune algorithm parameters based on human's response
 - continually adjust location and altitude of remaining QCs to restore perimeter coverage upon loss of QC
 - if coverage cannot be restored, request launch of backup QC

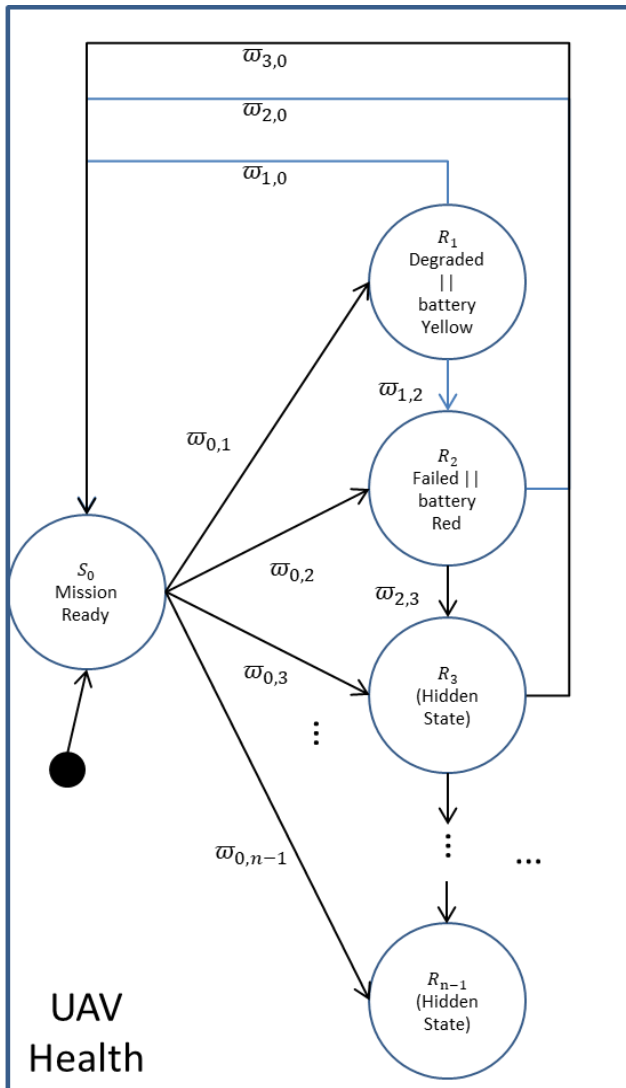

Segment #1: Navigating to Target Area

- QC Position relative to a reconnaissance target (red star) and FOV (blue)
- Employ appropriate models to cope with partial observability

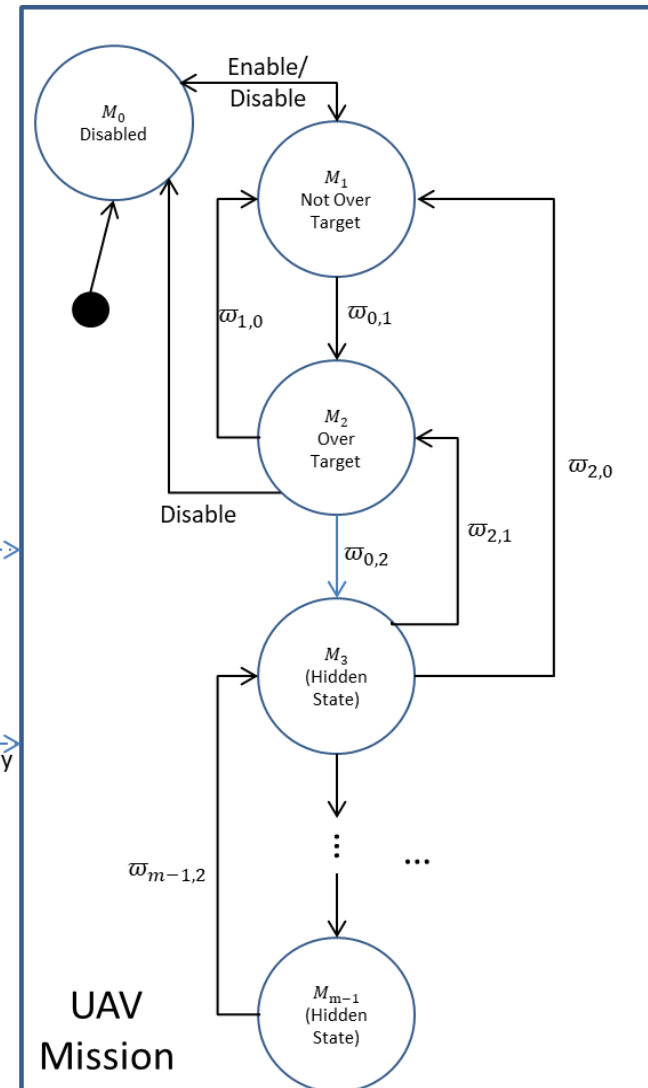

1. $\neg \text{overTarget} \ \&\& \ \text{healthy} \ \&\& \ \text{batteryGreen} \rightarrow \text{move_to_target}$
2. $\neg \text{batteryRed} \ \&\& \ \text{degraded} \ || \ \text{batteryYellow} \rightarrow \text{move_to_base}$
3. $\text{batteryRed} \ || \ \text{failed} \rightarrow \text{land}$
4. $\text{unknownHealth} \ || \ \text{unknownBattery} \rightarrow \text{move_to_base}$
5. $\text{overTarget} \ \&\& \ \text{CTR} \ \&\& \ \text{healthy} \rightarrow \text{takeImages} \ \& \ \text{hover}$
6. $\text{overTarget} \ \&\& \ \text{NW} \ \&\& \ \text{healthy} \rightarrow \text{takeImages} \ \& \ \text{move SE}$
7. $\text{overTarget} \ \&\& \ \text{NE} \ \&\& \ \text{healthy} \rightarrow \text{takeImages} \ \& \ \text{move SW}$
8. $\text{overTarget} \ \&\& \ \text{SW} \ \&\& \ \text{healthy} \rightarrow \text{takeImages} \ \& \ \text{move NE}$
9. $\text{overTarget} \ \&\& \ \text{SE} \ \&\& \ \text{healthy} \rightarrow \text{takeImages} \ \& \ \text{move NW}$

Simplified POMDPs: Health and Mission Models

Mission Ready

Mission not Ready

Maintain Perimeter Security

- Assure coordinated response by team members
 - Human-in-the-loop response for previously unseen situations
 - preplanned protocols between QCs for known patterns
- Continually adapt coverage in the face of disruptions
 - monitor and share health status of QCs (battery, comm links)
 - monitor disruptions (e.g., loss of a QC due to malfunction, low battery)
 - respond to disruptions (e.g., adjust locations and altitudes to restore coverage, request backup)

Fitness Function to Maximize Coverage

- Discretize perimeter area into tiles
 - goal: one or two cameras observing each tile (more than two is redundant and should not be rewarded)
 - closer coverage (higher resolution of imaging) is better
- Simple algorithm: for each tile and each camera
 - if tile is visible from camera, sum up $1/(\text{distance to camera})$
 - cap each tile sum to avoid rewarding redundant coverage
- Future improvements to fitness function
 - reward views from widely separate camera locations to maximize available information e.g. stereo
 - account for different camera capabilities e.g. higher resolution on fixed building cameras

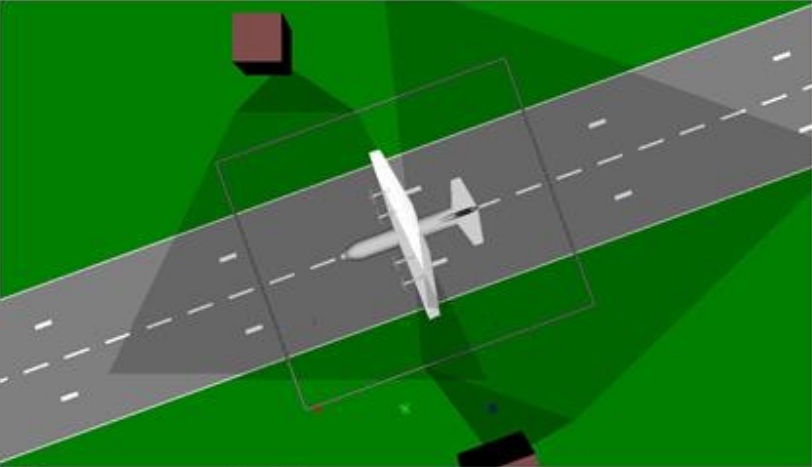

- Multi-agent control
 - multiple QCs move independently to maximize their contributions to the fitness function
 - resulting cooperative motion works to increase fitness
- Adaptation to changing circumstances
 - e.g., one QC crashes, or has low battery power and needs to land
 - other QCs move to restore loss of coverage
- Human-in-the-loop
 - if multi-agent control proves to be insufficient to provide adequate coverage, human intervention is requested
 - it is up to the human to act, e.g. launch additional QC, or request help from higher headquarters
 - if CPS cannot distinguish intruders from friendly troops, human intervention is requested

- Content and composition based on METT-TC ontology
 - Concepts and attributes of mission, enemy, troops, terrain (and weather), time available, and civilian population
 - Relationships between concepts
- Enables scenario setup, execution monitoring, visualization, resource allocation, control and supports supervised machine learning
 - Intrusion detection: detection of threats approaching aircraft/airfield perimeter
 - Monitoring of enemy combatants and / or unidentified moving objects (e.g., animals)
 - Threat tracking using available cameras (mobile, building-mounted)
 - Motion tracking and feature extraction of any moving objects
 - Agent-in-the-loop learning from human supervisor

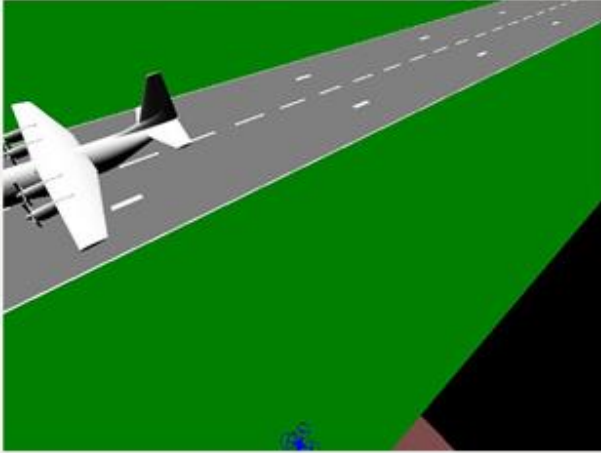

- Purpose
 - monitoring and control of multiple simulated and physical vehicles
- Underlying technologies
 - ontology-driven customizable interface
 - dronekit platform with visualization facilities
 - quadcopters (hardware) and quadcopter simulation models
 - quadcopter planning and decision-making model
 - quadcopter controller
 - decision tree for motion classification
- Key capabilities
 - simulated vehicles exhibit behavior of physical vehicle
 - same commands used to control vehicle models and the physical vehicles (quadcopters)
 - can switch from simulated to physical vehicles, and vice versa

- **Problem:** control the collection assets (UAVS and fixed cameras) to optimize multi-sensor coverage of the aircraft perimeter
- **Fitness function** to characterize perimeter coverage
 - Employs multiple levels to flexibly allocate and move assets to optimize coverage:
 - Multi-agent control
 - Adaptivity
 - Human-in-the-loop

- **Motion detection:** image analysis using open-source OpenCV computer vision software library
 - **Feature identification:** SIFT (Scale-Invariant Feature Transform)
 - **Optical flow:** Lucas-Kanade (LK) pyramid method

- **Agent-in-the-loop** learning from a **human supervisor**
 - Integration of **decision tree** within simulation dashboard
 - Invoked whenever a moving object is seen within the field of view of the active camera
 - Decision tree analysis of moving object produces three possible outcomes: friendly, enemy, or consult human supervisor
 - Data collected from human supervisor is used to tune the decision tree in a batch off-line learning mode
 - E.g. Classification accuracy was 0.567 initially that increased to 0.98 after tuning the parameters based on collected data.

- Developed concurrently with prototype system
- Currently supports system modeling, model verification, system behavior simulation, threat simulation
- Simulations runs on separate machines within a distributed, networked architecture

Implementation:

Distributed Simulation Architecture

- C-130 perimeter defense sim: distributed on 3 computers:
 - World server, Perimeter defense computer, Enemy computer
- World server
 - maintains state of all entities in the world
 - runs a continuous dynamic simulation of all QCs
- Perimeter defense computer
 - runs dashboard which controls the QCs
- Enemy computer
 - runs the enemy dashboard which controls enemy soldiers
- 2 dashboard computers communicate with world server to
 - obtain entity state (x,y,z,) to display all entities on screen
 - send motion commands to move entities they control
 - sensors modeled by defense dashboard

Technical Findings

- Key problem in implementing hybrid models
 - resolving mismatch between planning & decision-making layer and vehicle control layer
- Mismatch resolution
 - ensure that propagated commands from PDM layer to controller do not violate physical and regulatory constraints
 - propagate execution constraints from control layer to PDM layer for PDM layer to account for when issuing commands
 - incorporate heuristics (e.g., priorities, region of influence) to resolve conflicts and simplify computation
- POMDP and vehicle controller work on different time scales
 - dynamics model runs every 0.01 seconds (accuracy)
 - POMDP runs slower (high level decisions/commands)
 - waypoint navigation problem - minimize response time to action
 - ideal sampling period for POMDP determined experimentally

- Concurrent creation of dashboard and testbed was a plus
 - enabled rapid iterations on dashboard design
 - dashboard is an essential component of adaptive CPHS and debugging aid
 - enabled early demos of evolving system to DoD, SERC, and transition partner
 - gained valuable experience to create MBSE testbed for SERC community
- Model type and complexity are a function of problem context
 - size of system state-space
 - knowledge of system states
 - environment observability and uncertainty
- Even a relatively simple fitness function yielded promising results
 - can develop more sophisticated fitness functions in the future
- What next?
 - incorporate physical system data into virtual model to create Digital Twin
 - enhance verification and testing - expand MBSE coverage of system life cycle

- DoD systems in 21st century need to be resilient and operate safely in uncertain, partially observable, potentially hostile environments
- Adaptive CPHS, an example of a 21st century system, poses unique modeling, analysis and realization challenges
- Adaptation implies not only changes in model parameters but also modeling construct (“principle of proportional complexity”)
- Distributed simulation well-suited to implementing adaptive CPHS
- Approach successfully applied to perimeter security of military aircraft
- Successfully demonstrated supervisory and autonomous control of QCs
- Demonstrated value of a context-aware dashboard in maximizing situation awareness and exploring what-ifs
- **Successful Transition:** Research product along with product of RT-166/210 transitioned to The Aerospace Corporation’s MBSE team

- Founder and CEO, Intelligent Systems Technology Inc.
- INCOSE Fellow, Pioneer and Founder
- Life Fellow, IEEE; Fellow, AAAS; Fellow, AIAA; Life Fellow, SDPS; Life Fellow, IETE
- Ph.D., M.S., B.S. in Engineering, UCLA; Graduate of Stanford's Executive Program
- **Research Interests:** Formal and Probabilistic System Modeling; Resilient Cyber-Physical-Human Systems; Interactive Storytelling in Virtual Worlds, Intelligent Systems Engineering
- **2019 Awards and Honors**
 - *2019 Presidential Award from Society of Modeling and Simulation International*
 - *2019 AIAA/ASEE Leland Atwood Award* for excellence in aerospace engineering
 - *2019 ASME CIE Leadership Award* for advancing use of computers in engineering
 - *2019 INCOSE Founders Award* for increasing global awareness of INCOSE
 - *2019 EC William B. Johnson International Inter-Professional Founders Award*
 - *2019 OCEC Prestigious Pioneering Educator Award*
- **Recent Books**
 - Madni, A.M., Boehm, B. et al. (eds.) *Disciplinary Convergence: Implications for Systems Engineering Research*, Springer, 2018.
 - *Transdisciplinary Systems Engineering: Exploiting Convergence in a Hyper-Connected World* (foreword by Norm Augustine) Springer, 2017
 - *Tradeoff Decisions in System Design* (foreword by John Slaughter), Springer, 2016
 - Madni, A.M. and Boehm, B. (eds), "*Engineered Resilient Systems: Challenges and Opportunities in the 21st Century*," *Procedia Computer Science* 28 (2014), ISSN 1877-0509, Elsevier, 2014

Thank You
